

OPTICAL FIBER FOR WDM SYSTEM AND MANUFACTURING METHOD THEREOF

BACKGROUND OF THE INVENTION

5 Field of the Invention

The present invention relates to an optical fiber used for wavelength-division multiplexing (WDM) optical transmission, or more particularly, to a ~~metropolitan-based~~ metropolitan system optical fiber and manufacturing method
10 thereof.

Description of the Related Art

Conventionally, a technology for increasing a transmission capacity in optical transmission using an optical
15 fiber has been pursued actively.

A transmission loss of an optical fiber generally reaches a minimum at a wavelength of approximately 1550 nm, and therefore it is desirable to use this wavelength band for optical transmission and a dispersion ~~[[shift]]~~ shifted
20 optical fiber (DSF) having a zero dispersion wavelength ~~close to~~ around a wavelength of 1550 nm has been developed. This optical fiber allows optical transmission with a transmission capacity of several Gbps in a wavelength band of 1.55 μm .

Furthermore, quite vigorous research and development on
25 wavelength-division multiplexing (WDM) optical transmission is being carried out as the technology for increasing a transmission capacity in recent years. Moreover, many

investigations are also being carried out on an optical fiber preferably used for WDM optical transmission.

When an optical fiber is used for WDM optical transmission, it is required from the standpoint of preventing a mixture
5 ~~of four light waves~~ four-wave mixing that no zero dispersion wavelength should exist in the wavelength band used, and therefore a non-zero dispersion ~~[[shift]]~~ shifted optical fiber (NZDSF) with no zero dispersion included in the wavelength band used has been developed. Through the
10 development of this NZDSF, WDM transmission has become feasible in a wavelength range of 1530 to 1565 nm (C band) and a wavelength range of 1565 nm to 1625 nm (L band), which has increased a transmission capacity drastically.

In order to increase the transmission capacity in such
15 a WDM optical transmission system, an attempt is made to ~~provide~~ expand a ~~[[wider]]~~ wavelength bandwidth of ~~signal light~~ transmission signals.

The invention disclosed in US Patent No. 6205268 maintains substantially the same fiber parameters as those of a standard
20 single mode optical fiber as shown in a loss curve 132 and dispersion curve 131 in FIG. 13, reduces a loss peak (133 in FIG. 13) by OH absorption of 1383 nm, reduces a dispersion value of a wavelength band of 1.4 μm and thereby realizes a CWDM (Coarse Wavelength Division Multiplexing) system in a
25 wide wavelength range of wavelength bands of 1.3 μm , 1.4 μm and 1.5 μm . In this CWDM transmission system, the optical fiber has a zero dispersion wavelength in the vicinity of 1310 nm (dispersion curve 131), and therefore ~~there is a proposal~~

ef transmission using the wavelength band of 1.3 μm for analog
CATV transmission and the wavelength band of 1.4 μm for
transmission at 10 Gbps or above is proposed. Furthermore,
with the proposal of this new CWDM transmission system, a
5 transmission apparatus ~~indispensable to a DWDM (Dense-
Wavelength Division Multiplexing)~~ for transmission in the
wavelength band of 1.4 μm has also been developed in recent
years and being put to practical use.

With consideration given to the application of WDM
10 transmission to a metropolitan system, given the fact that
an overwhelming majority of transmission paths running today
are standard single mode fibers, the proposal of above
described US Patent No. 6205268 seems excellent. However,
given the fact that an overwhelming majority of transmission
15 apparatuses already put to practical use are also transmission
apparatuses for the wavelength band of 1.3 μm , it is desirable
to use not only the wavelength band of 1.4 μm but also the
wavelength band of 1.3 μm for WDM transmission from the
standpoints of cost as well as consistency with the actual
20 system.

On the other hand, as the invention disclosed in US Patent
No. 5905838, there is a proposal on an optical fiber which
shifts the zero-dispersion wavelength to 1350 to 1450 nm as
shown in the dispersion curve 134 in FIG. 13 and sets an absolute
25 value of dispersion of 1310 nm and 1550 nm to 1.0 to 8.0 ps/nm/km
to thereby realize WDM transmission using both wavelength bands.
However, attempting to realize WDM transmission using both
wavelength bands results in an unavoidable reduction of the

mode field diameter MFD (or effective core area A_{eff}) as described in the aforementioned US Patent. The above described US Patent regards $49 \mu m^2$ as an upper limit of A_{eff} .

Furthermore, US Patent No. 6131415 sets a cladding/core ratio of a core rod to 2.0 to 7.5 to prevent OH groups in an over cladding from spreading into the core during drawing and realize a low OH fiber. However, it is generally known that an absorption peak by OH groups increases ~~[[when]]~~ after a hydrogen aging test specified by IEC60793-2-50 (first edition 2002-01) Annex C Section C 3.1 is conducted.

Especially when use in a metropolitan system is considered, the following conditions are further required:

(1) Many standard single mode optical fibers are already laid and ~~consistency~~ compatibility with these established optical fibers is important. For this reason, it is desirable to design that make a compatible design with the standard single mode optical fibers, regarding optical fiber parameters such as MFD, cladding diameter, specific refractive index difference and transmission characteristics such as optical transmission loss, dispersion, cutoff wavelength and mechanical characteristics such as against bending and lateral pressure be the same as those of a standard single mode fiber etc.

(2) Optical fibers are generally formed into a cable and laid in underground conduits. In the case of a metropolitan system, conduits are tangled in a complicated manner and it is difficult to lay the optical ~~fibers~~ cables in long lengths. For this reason, an average length of a cable piece is about 1 km. On the other hand, optical fibers are shipped in piece lengths

of 25 to 50 km. Normally, an absorption loss characteristic of 1383 nm by OH ~~never changes~~ groups does not change by ~~transformation into a cable~~ cabling, and therefore uniformity in the longitudinal direction of the transmission

5 characteristic of an optical fiber is an important factor to secure the quality of the cable.

In the case of a metropolitan system, multi-core cables ~~such as having~~ 1000 cores are put to practical use and ~~rather than transmission loss~~, it is more important for the optical
10 fiber to have excellent uniformity in the characteristic (transmission loss) of approximately 1 km, small loss in connections between fibers, micro bending loss and resistance to lateral pressures, etc., rather than an average transmission loss in long length of 25 to 50 km. From such a standpoint,
15 ~~in the optical fiber proposed in above described US Patent No. 5905838, uniformity of the characteristic of a short fiber is not always guaranteed~~ it does not disclose transmission characteristics in short length of the optical fiber and the MFD (A_{eff}) is as small as approximately 7 μm , and therefore
20 connection loss in a connection with a standard single mode optical fiber having an MFD of approximately 9.2 μm becomes 0.3 dB or above, which is not practical. In this way, attempting to ~~achieve perfect consistency~~ be compatible with existing transmission paths results in ~~inconsistency~~ not being
25 compatible in terms of transmission apparatuses, and on the contrary attempting to ~~achieve perfect consistency~~ be compatible with existing transmission apparatuses results in ~~inconsistency~~ not being compatible in terms of transmission

paths. Any attempt to optimize this ~~consistency~~
compatibility from both aspects of transmission paths and
transmission apparatuses has not been made so far.

5

SUMMARY OF THE INVENTION

The present invention has been implemented taking into
account the uniformity of transmission loss for longitudinal
direction (i.e., longitudinal uniformity) in 1383 nm of a short
fiber of approximately 1 km long and mainly ~~consistency~~
10 compatibility with existing optical fibers as a metropolitan
optical fiber.

The present ~~inventor et al.~~ inventors noticed the
longitudinal uniformity in transmission loss at a wavelength
of 1383 nm which is an absorption peak of OH groups and ~~developed~~
15 ~~its measuring technology~~ and investigated into the
longitudinal uniformity of transmission loss ~~[[in]]~~ at this
wavelength ~~[[band]]~~ of 1383 nm by using the developed
measurement technology, and as a result discovered the
following points:

20 For example, ~~[[with]]~~ though an optical fiber of 25.2
km ~~[[long,]]~~ length band and average transmission loss at a
wavelength of 1383 nm ~~[[is]]~~ of 0.32 dB/km with substantially
no absorption peak of OH groups, a measurement result of section
loss for every 1 km ~~showed that there was~~ were measured with
25 a large variation of 0.28 to 0.38 dB/km (see FIG. 3). When
longitudinal uniformity of transmission loss of this optical
fiber at wavelength of 1310 nm and wavelength of 1550 nm was
measured, with regard to section loss for every 1 km, the

variation width from an average transmission loss fell within a range of 0.03 dB/km. For this reason, it has been discovered that while the conventional optical fiber could guarantee transmission loss in ~~a short fiber~~ a short length of optical fiber at a wavelength of 1310 nm or 1550 nm, it could not necessarily guarantee transmission loss in ~~a short fiber~~ a short length of optical fiber at a wavelength of 1383 nm.

It has also been discovered that as with an Aeff expansion type NZDSF and a dispersion slope reduction type NZDSF, a longitudinal variation of transmission loss of this wavelength band of 1383 nm tends to increase in size as a profile of the optical fiber becomes more complicated.

One aspect of the present invention is to provide an optical fiber with a reduced variation in the longitudinal direction of transmission loss at the above described wavelength of 1383 nm ~~reduced~~. The optical fiber according to the present invention is an optical fiber having a length of 1 km or more with an average transmission loss at a wavelength of 1383 nm being less than an average transmission loss in a wavelength of 1310 nm, characterized in that a maximum value of section loss of any 1 km at a wavelength of 1383 nm does not exceed the average transmission loss by 0.03 dB/km or more. The maximum value of any section loss of any 1 km at the wavelength of 1383 nm preferably does not exceed the average transmission loss by 0.01 dB/km or more.

Furthermore, the optical fiber according to the present invention is characterized in that the cutoff wavelength [[in]] at a length of 22 m is less than 1380 nm.

Furthermore, the optical fiber according to the present invention is characterized in that the average transmission loss at a wavelength of 1383 nm ~~after a hydrogen aging test~~ is less than an average transmission loss at the wavelength of 1310 nm after a hydrogen aging.

According to the optical fiber of the present invention, the average transmission loss at the wavelength of 1383 nm is less than the average transmission loss at the wavelength of 1310 nm and the maximum value of any 1 km section loss does not exceed the average transmission loss by 0.03 dB/km or more, and therefore it can be used [[in]] at a wavelength band of 1.38 μ m and transmission loss can be guaranteed even ~~with a short cable~~ for a short length of cable.

Furthermore, since the cutoff length at a length of 22 m is shorter than 1380 nm, single mode transmission at a wavelength of 1383 nm is possible.

Furthermore, since the average transmission loss at the wavelength of 1383 nm ~~after a hydrogen aging test~~ is less than the average transmission loss at a wavelength of 1310 nm after a hydrogen aging, stable transmission in a wavelength band of 1.38 μ m for a long period of time can be guaranteed.

In the present specification, average transmission loss (dB/km) ~~refers to a value obtained~~ is defined as a value obtained by dividing a transmission loss (dB) ~~of one continuous~~ along the entire length of an optical fiber (that is, length not

including ~~connection parts~~, splicing point for example, one turn length) by the continuous length (km). Furthermore, an ~~arbitrary~~ any 1 km section (dB/km) loss refers to is defined as a transmission loss of arbitrary at any 1 km section in the longitudinal direction. Furthermore, a hydrogen aging test refers to a method specified by IEC60793-2-50 (first edition 2002-01) C3.1. ~~Here, suppose~~ Suppose λ in the present invention is 1383 nm. Furthermore, a cable cutoff wavelength at a length of 22 m refers to a cable cutoff wavelength λ_{cc} defined in ITU-T G.650. ~~Suppose other~~ Other terms not defined in this ~~[[text]]~~ specification will follow definitions and measuring methods according to ITU-T G.650.

A second aspect of the present invention is to provide an optical fiber which is preferably applicable to DWDM transmission in a wavelength band of 1.3 μm ~~having consistency~~ that is compatible with existing transmission paths (standard single mode fiber).

The optical fiber of the present invention is characterized by having an MFD of 8 μm or more at a wavelength of 1310 nm, ~~[[no]]~~ a zero dispersion wavelength ~~[[in]]~~ out of a wavelength range of 1280 to 1324 nm, a dispersion absolute value in the wavelength range of 0.1 to 8.0 ps/nm/km, a dispersion slope of 0.1 ps/nm²/km or less, a cable cutoff wavelength ~~according to a~~ at a length of 22 m ~~method of~~ 1270 nm or less and average transmission loss of 0.4 dB/km or less at a wavelength of 1310 nm. Here, a wavelength band of 1.3 μm ~~refers to~~ is defined as a range of wavelength of 1280 nm to 1324 nm.

Since the MFD at 1310 nm is 8 μm or above, it is possible to reduce a ~~connection~~ splicing loss with ~~respect to~~ a standard single mode optical fiber ~~[[whose]]~~ having MFD ~~[[is]]~~ of approximately 9.2 μm to 0.1 dB or below and maintain ~~consistency~~ compatibility with existing transmission paths.

Furthermore, since there is ~~[[no]]~~ zero dispersion wavelength ~~[[in]]~~ out of at a wavelength range of 1280 to 1324 nm and a dispersion in the wavelength range is 0.1 to 8.0 ps/nm/km, it is possible to practically ignore waveform distortion due to a nonlinear phenomenon such as a ~~mixture of four light waves~~ four-wave mixing, etc. Since the absolute value of the dispersion slope is 0.1 ps/nm²/km or less, the difference in the wavelength dispersion value between signal ~~light beams~~ lights is reduced and optical transmission which effectively reduces the difference in the amount of waveform distortion by wavelength dispersion between signal ~~light beams~~ lights becomes feasible.

Since the cutoff wavelength at a length of 22 m is 1270 nm or less ~~according to the 22 m method~~, only ~~[[base]]~~ a fundamental mode light ~~in at a wavelength band of 1.3 μm~~ can propagate in a wavelength band of 1.3 μm . Since the average transmission loss at a wavelength of 1310 nm is 0.4 dB/km or less, an optical communication in a wavelength band of 1.3 μm is possible.

Furthermore, when the MFD at 1310 nm is 9.5 μm or less or when the zero dispersion ~~length~~ wavelength is 1325 to 1350 nm, the optical fiber of the present invention can be realized by only adding a minimum change to the profile of the standard

single mode optical fiber, making it possible to realize an optical fiber with excellent manufacturability.

Furthermore, with the optical fiber of the present invention, when an MFD at 1310 nm is A (μm) and a cable cutoff wavelength according to the 22 m method at a length of 22 m is B (nm), it is possible to realize the above described characteristic by satisfying a relationship of $A \times B \leq 11 \times 1000$.

Furthermore, ~~[[with]]~~ when the optical fiber of the present invention~~[[,]]~~ has the average transmission loss at a wavelength of 1383 nm that is less than the average transmission loss at a wavelength of 1310 nm, ~~and therefore by setting~~ the absolute value of dispersion ~~[[to]]~~ of 0.1 to 8.0 ps/nm/km and ~~setting~~ the dispersion slope ~~[[to]]~~ of 0.1 ps/nm²/km or less, it is possible to utilize a wavelength band of 1.4 μm ~~[[in a]]~~ for future expansion of the wavelength range, which is therefore preferable.

Since an increase in average transmission loss at a wavelength of 1383 nm ~~from before to after a hydrogen aging test~~ is 0.04 dB/km or less after hydrogen aging, it is possible to provide an optical fiber with excellent long-term reliability accompanied by hydrogen resistance.

A third aspect of the present invention is intended to provide a fiber which has only a small increase of an absorption peak by OH groups at 1383 nm even if a hydrogen aging test is conducted, that is, a fiber with excellent hydrogen resistance and consistent with existing optical fibers as a metropolitan fiber. It is especially intended to provide a

method of manufacturing an optical fiber preferably applicable to a WDM transmission in a C band at low costs.

In order to attain the above described objects, the present invention provides a method of manufacturing an optical fiber
5 having a mode field diameter of 8.0 to 11.0 μm at a wavelength of 1310 nm, average transmission loss at a wavelength of 1383 nm ~~[[being]]~~ less than average transmission loss at a wavelength of 1310 nm and dispersion of +2 to +8 ps/nm/km at a wavelength of 1383 nm, characterized ~~in that~~ by drawing an
10 optical fiber base material is drawn preform, coated and the optical fiber strand obtained is subjected to exposure in coating the optical fiber and exposing the optical fiber to
a vapor phase atmosphere containing a deuterium gas.

In the optical fiber provided with the above described
15 characteristics, those characteristics are used for the following reasons:

(1) First, the MFD at a wavelength of 1310 nm is designed to be 8.0 to 11.0 μm and this is intended to secure ~~consistency~~ compatibility when connected to an existing standard single
20 mode optical fiber.

(2) The average transmission loss at the wavelength of 1383 nm is designed to be less than the average transmission loss at the wavelength of 1310 nm. Thus, an increase in transmission loss at the wavelength of 1383 nm is suppressed.

25 This is realized by applying a process which will be described later and thereby suppressing an increase in absorption loss by OH groups at the wavelength of 1383 nm.

(3) Dispersion in the wavelength range of wavelength of 1383 nm is designed to be +2 to +8 ps/nm/km. The optical fiber is preferably designed to have a dispersion of +4 to +7 ps/nm/km at the wavelength of 1383 nm.

5 This can suppress influences of a ~~mixture of four light waves~~ four-wave mixing and minimize influences of accumulated dispersion when an optical transmission path is constructed.

As long as the above described characteristics are satisfied for the optical fiber manufactured according to the
10 present invention, the shape of a refractive index distribution profile is subject to no restrictions. For example, the refractive index ~~distribution~~ profile applied to a low loss optical fiber shown in FIG. 1 can be used.

15 BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates a refractive index profile of an optical fiber in an embodiment according to a first aspect of the present invention;

FIG. 2 illustrates a refractive index profile of
20 multilayer cores of an optical fiber in another embodiment according to the first aspect of the present invention;

FIG. 3 illustrates a section loss variation for every 1 km of transmission loss at a wavelength of 1383 nm in a conventional optical fiber;

25 FIG. 4 illustrates a refractive index profile of an optical fiber in an embodiment according to a second aspect of the present invention;

FIG. 5 illustrates a refractive index profile of an optical fiber in another embodiment according to the second aspect of the present invention;

FIG. 6 illustrates a refractive index profile of an optical fiber in an embodiment according to a third aspect of the present invention;

FIG. 7 is an example of a transmission loss spectrum of an optical fiber with drawing and with an extremely small amount of OH groups;

FIG. 8 is an example of a transmission loss spectrum when D_2 processing is applied to an optical fiber;

FIG. 9 is a graph showing a relationship between a transmission loss variation and D_2 processing time after D_2 processing is started;

FIG. 10 illustrates a transmission loss spectrum of an optical fiber before D_2 processing;

FIG. 11 illustrates a transmission loss spectrum of an optical fiber after D_2 processing;

FIG. 12 is a graph showing a relationship between a transmission loss difference at a wavelength of 1420 nm from before to after D_2 processing and elapsed time after the D_2 processing is started; and

FIG. 13 illustrates a dispersion characteristic and transmission loss characteristic of a conventional optical fiber.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference now to the attached drawings, a first aspect of an optical fiber of the present invention that reduces a transmission loss variation at a wavelength of 1383 nm and a method of manufacturing thereof will be explained below.

5 FIG. 1 illustrates a refractive index profile of an optical fiber according to the present invention. ~~[[As]]~~ Thereby as a result of investigations into the above described problem of the longitudinal variation of transmission loss at a wavelength of 1383 nm, the present ~~inventor et al.~~ inventors

10 have discovered that micro variations in the core diameter and the amount of core eccentricity in the longitudinal direction ~~[[in]]~~ at the stage of the base material of the optical fiber preform were the causes for the problem. OH groups in the over cladding generally spread toward the core during

15 drawing and the area close to the over cladding has a higher concentration of OH group. ~~The area where light propagates up to the vicinity of the~~ light propagation region near the area close to over cladding with a higher concentration of OH group extends more in an area where the mode field diameter

20 is large than an area where the mode field diameter is small, and therefore the transmission loss at ~~[[a]]~~ the wavelength of 1383 nm is liable to increase. Thus, a longitudinal variation of transmission loss at ~~[[a]]~~ the wavelength of 1383 nm occurs according to the variation of the mode field diameter.

25 As described in US Patent No. 6131415, it is disclosed that increasing the cladding/core ratio in a core rod is effective in reducing an average transmission loss at ~~[[a]]~~ the wavelength of 1383 nm. However, increasing the

cladding/core ratio in the core rod causes a micro variation of the cladding/core ratio to lead to an increase of the MFD or the length of a variation in the amount of mode field eccentricity. To improve these contradictory

5 characteristics, the following changes have been made in the design of a standard single mode optical fiber.

1) Using a VAD method, the cladding/core ratio when the core rod was manufactured was set to 2 or below. This managed to suppress influences of the variation in the cladding/core ratio
10 on the longitudinal direction to 1 km or less.

2) In the elongation ~~[[step]]~~ process, etc., an elongation was made using an electric furnace without using any oxy-hydrogen flame burner. Avoiding the use of the oxy-hydrogen flame burner which may cause OH allowed the
15 concentration of OH ~~[[group]]~~ groups of the entire glass to be reduced to 1 ppm or below.

3) As shown in FIG. 1, ~~[[an]]~~ a range of a second cladding
13 obtained by ~~glassifying~~ vitriifying a porous soot body of a small bulk density was ~~placed~~ disposed at the midpoint
20 position between the core rod (core 11 and first cladding 12) and the outermost third cladding 14. The ratio of diameter of the core 11 to the second cladding 13 was set to 6 to 8. The bulk density of the range of the second cladding 13 ~~in~~
~~the~~ at the stage of the porous soot ~~[[stage]]~~ body is preferably
25 0.3 g/cm³ or less. This also allowed the concentration of OH ~~[[group]]~~ groups of the second cladding 13 to be reduced to 1 ppm or below.

The optical fiber ~~base material~~ preform obtained in this way was drawn into an optical fiber and the ~~characteristic characteristics~~ thereof ~~was checked~~ were measured as follows. The following ~~result~~ results ~~[[was]]~~ were obtained, which
5 ~~indicates~~ indicate that the optical fiber is also applicable to a short ~~[[cable]]~~ length of optical cables.

Transmission loss at 1310 nm: 0.34 dB/km
Transmission loss at 1550 nm: 0.20 dB/km
Transmission loss at 1383 nm: 0.31 dB/km
10 Maximum value of 1 km section loss:
 at 1310 nm: 0.36 dB/km
 at 1550 nm: 0.21 dB/km
 at 1383 nm: 0.32 dB/km

MFD:
15 at 1310 nm: 9.2 μm
 at 1550 nm: 10.4 μm
 at 1383 nm: 9.6 μm

This technique was applied to the profile in FIG. 2 and an effective ~~sectional~~ area (A_{eff}) ~~expansion~~ enlarged type
20 of NZDSF and a dispersion slope ~~reduction~~ reduced type of NZDSF were ~~created~~ made as prototypes. That is, the refractive index profile 21 shown in FIG. 2 is a refractive index profile with multilayer cores corresponding to the core 11 shown in FIG. 1. Even in such a case with a multilayer core, the result
25 showed that by providing the second cladding layer 13 shown in FIG. 1, the maximum value of any 1 km section loss at a wavelength of 1383 nm ~~would never~~ did not exceed the average transmission loss by 0.03 dB/km or more.

According to the optical fiber of the present invention, the average transmission loss at the wavelength of 1383 nm is less than the average transmission loss at a wavelength of 1310 nm and the maximum value of any 1 km section loss does not exceed the average transmission loss by 0.03 dB/km or more, and therefore the optical fiber can be used at a wavelength of 1383 nm and transmission loss can be guaranteed even in the case of a short length of optical cable. Furthermore, since the average transmission loss at the wavelength of 1383 nm after a hydrogen aging test is less than the average transmission loss at a wavelength of 1310 nm, it is possible to guarantee a stable transmission for a long period of time in the vicinity of approximately 1380 nm.

Then, for the ~~consistency~~ compatibility of the present invention with existing fibers, an example of the optical fiber with ~~[[a side]]~~ an aspect with an MFD of 8 μ m or more at 1310 nm will be explained with reference to FIG. 4 and FIG. 5.

The optical fiber according to the present invention ~~is preferably applicable to a case where~~ has preferably the MFD at 1310 nm ~~[[is]]~~ of 9.5 μ m or less or ~~[[where]]~~ the zero dispersion ~~length is~~ wavelength of 1325 to 1350 μ m. The above described characteristic can be realized by satisfying a relationship of $A \times B \leq 11 \times 1000$ when the MFD at the wavelength of 1310 nm is A (μ m) and the cutoff wavelength ~~according to the 22-m method~~ at a length of 22 meters is B (nm).

Furthermore, with the optical fiber according to the present invention, it is preferable that the average transmission loss at the wavelength of 1383 nm be less than

the average transmission loss at the wavelength of 1310 nm and the absolute value of dispersion be 0.1 to 8.0 ps/nm/km and the dispersion slope be 0.1 ps/nm²/km or below.

By ~~setting an increase in~~ reducing a transmission loss
5 at the wavelength of 1383 nm ~~from before to after the hydrogen~~
~~aging test to 0.04 dB/km or below~~ after hydrogen aging to 0.04
dB/km or less, the present invention can provide an optical
fiber with excellent long-term reliability, which is therefore
preferable.

10 The optical fiber according to this embodiment comprises
a core ~~[[area]]~~ having a refractive index of n_1 centered on
the optical axis and a cladding ~~[[area]]~~ having a refractive
index of n_2 around the core area. The relationship between
those refractive indices is $n_1 > n_2$. Such an optical fiber
15 can be realized ~~using silica as the base and adding, for example,~~
~~Ge element to the core area~~ by doping Germanium to the silica
core.

For the optical fiber, the soot produced by a VAD method
was ~~classified~~ vitriified through dehydration, ~~sintering~~
20 sintered to obtain a preform, then the preform was drawn and
coated with two UV cure resin layers to obtain an optical fiber
strand of 250 μm in outer diameter. Then, the optical fiber
was ~~left standing~~ exposed in a ~~[[D2]]~~ D_2 gas atmosphere at
~~a normal~~ an ordinary temperature and under ~~a normal~~ an ordinary
25 pressure for approximately 2 hours and ~~checked~~ measured for
the various characteristics shown below.

[First Example]

The optical fiber according to First Example has the refractive index profile made up of a step type core refractive index 41 and a cladding refractive index 42 shown in FIG. 4, wherein the MFD at a wavelength of 1310 nm is 8.5 μm , the zero dispersion wavelength is 1326 nm, the dispersion slope in a wavelength range of 1280 nm to 1324 nm is 0.08 ps/nm²/km, the absolute value of the dispersion value in the wavelength range is 0.4 to 3.4 ps/nm/km and the cutoff wavelength is 1250 nm. Therefore, A \times B (product of MFD and cutoff wavelength) is ~~10600~~ was 10625. The average transmission loss at the wavelength of 1310 nm was 0.34 dB/km and the average transmission loss at the wavelength of 1383 nm was 0.29 dB/km. Furthermore, ~~[[when]]~~ after a hydrogen aging test was conducted on this fiber, the increase in transmission loss at the wavelength of 1383 nm ~~from before to after the test~~ was 0.00 dB/km.

[Second Example]

The optical fiber of Second Example has the refractive index profile shown in FIG. 4, wherein the MFD at a wavelength of 1310 nm is 8.1 μm , the zero dispersion wavelength is 1340 nm, the dispersion slope in a wavelength band of 1.3 μm is 0.08 ps/nm²/km, the absolute value of the dispersion value in the wavelength band of 1.3 μm is 1.6 to 5.2 ps/nm/km and the cutoff wavelength is 1100 nm. Therefore, A \times B (product of MFD and cutoff wavelength) is ~~[[8900]]~~ 8910. The average transmission loss at the wavelength of 1310 nm was 0.34 dB/km and the average transmission loss at the wavelength of 1383 nm was 0.29 dB/km. Furthermore, ~~[[when]]~~ after a hydrogen

aging test ~~was conducted~~ on this fiber, the increase in transmission loss at the wavelength of 1383 nm ~~from before to after the test~~ was 0.00 dB/km.

[Third Example]

5 The refractive index profile of the optical fiber according to the present invention is not limited to the one shown in FIG. 4, but, for example, the [[one]] refractive index profile shown in FIG. 5 is also acceptable. This is a profile having a first core refractive index 51 with a peak at the center, a refractive index which is greater than a cladding refractive index 54 by $\Delta 1$, a second core refractive index 52 which is smaller by $\Delta 2$ and a third core refractive index 53 which is greater than the cladding by $\Delta 3$.

15 The fiber of the present invention can ~~maintain~~ consistency be compatible with existing transmission paths and provides a WDM optical fiber which suppresses generation of a ~~mixture of four light waves~~ four-wave mixing in a wavelength band of 1.3 μm .

20 Furthermore, when the MFD [[in]] at a wavelength of 1310 nm is 9.5 μm or below or when the zero dispersion wavelength is 1325 to 1350 nm, the optical fiber of the present invention can realize an optical fiber with excellent manufacturability, which is therefore preferable.

25 Furthermore, having the average transmission loss at a wavelength of 1383 nm being less than the average transmission loss at a wavelength of 1310 nm, the absolute value of the dispersion of 0.1 to 8.0 ps/nm/km and the dispersion slope of 0.1 ps/nm²/km or below, the optical fiber of the present

invention can thereby utilize a wavelength band of 1.4 μm when the wavelength ~~[[range]]~~ area used ~~[[is]]~~ will be expanded in the future, which is therefore preferable.

When the increase in average transmission loss at the
5 wavelength of 1383 nm ~~from before to~~ after a hydrogen aging test is 0.04 dB/km or below, the present invention can provide an optical fiber with excellent long-term reliability, which is further preferable.

An example of implementation of a method of manufacturing
10 a metropolitan optical fiber with excellent hydrogen resistance according to the third aspect of the present invention is as follows.

First, an optical fiber ~~base material~~ preform is manufactured using a conventional VAD method ~~as in the case~~
15 ~~of the conventional one.~~ Then, the optical fiber ~~base material~~ preform is drawn and an optical fiber having a predetermined ~~[[wire]]~~ diameter is manufactured and then the optical fiber is coated to be transformed into an optical fiber ~~[[strand]]~~. Then, this optical fiber ~~[[strand]]~~ is processed to improve
20 hydrogen resistance. More specifically, this optical fiber ~~[[strand]]~~ is accommodated in a processing apparatus and the inside of the apparatus is set in an atmosphere ~~including~~ containing a deuterium ~~[[(D₂)]]~~ (D₂) gas at ~~a normal~~ an ordinary temperature and under ~~a normal~~ an ordinary pressure and left
25 ~~standing~~ exposed for a predetermined time.

The deuterium component is charged into the optical fiber ~~body of the optical fiber strand~~, infiltrates into defects in the optical fiber ~~[[body]]~~ and forms ~~bonding~~ coupling. As

a result, when the processed optical fiber ~~[[strand]]~~ is subjected to a hydrogen aging test, hydrogen that has infiltrated into the optical fiber ~~[[body]]~~ cannot couple with the above described defects which are already inactivated, and therefore no increase of any specific absorption peak occurs. That is, hydrogen resistance is improved.

It is preferable to ~~[[use]]~~ set 10 to 40°C as the ~~normal~~ ordinary temperature and 86 to 106 kPa as the ~~normal~~ ordinary pressure during the above described exposure processing. The processing time is ~~changed according to~~ dependent on the length of the optical fiber ~~strand~~ to be processed and ~~carrying out processing for 24 hours at longest is enough.~~

By carrying out such processing, the present invention can provide an optical fiber having the above described characteristics, wherein the amount of increase in transmission loss at the wavelength of 1383 nm after a hydrogen aging test is 0.04 dB/km or ~~below and further~~ less, preferably 0.01 dB/km or ~~[[below]]~~ less.

A refractive index ~~distribution~~ profile of the optical fiber manufactured in this way is shown in FIG. 6 and is of a step type with a core 61 having a higher refractive index than a cladding 62.

This optical fiber ~~strand~~ at a length of approximately 3 km long is placed in the processing apparatus, the inside of the apparatus is set in a substantially 100% deuterium atmosphere at a temperature of 23°C and under a pressure of 100 kPa and left in that condition for approximately 3 hours.

The optical fiber ~~strand~~ after the processing was subjected to a hydrogen aging test specified ~~[[by]]~~ in IEC60793-2-50 (first edition 2002-01) Annex C Section C 3.1 and the average transmission loss at the wavelength of 1383 nm was measured using the method specified by ITU-TG.650. This result is shown together with the measurement result before ~~the test~~ the hydrogen aging in Table 1. The average transmission loss at the wavelength of 1310 nm was also measured.

The MFD at the wavelength of 1310 nm and the dispersion value at the wavelength of 1383 nm were measured and their results are also shown in Table 1. For comparison, similar measurements are also performed on the optical fiber ~~strand~~ without deuterium exposure processing and the results are shown together as a comparative example.

[Table 1]

	Refractive index distribution profile	Dispersion value (ps/nm/km)	MFD (μm)	Transmission loss at the wavelength of 1310 nm (dB/km)	Transmission loss at the wavelength of 1383 nm (dB/km)	
					Before hydrogen aging test	After hydrogen aging test
Example 1	FIG. 6	5.8	9.26	0.33	0.31	0.31
Example 2	FIG. 6	4.5	9.38	0.32	0.29	0.29
Comparative Example	FIG. 6	5.1	9.14	0.33	0.29	0.39

As is apparent from Table 1, in comparison with the comparative example with no deuterium processing, the optical fiber manufactured by the method of the present invention has no increase in average transmission loss at a wavelength of 1383 nm ~~from before to~~ after the hydrogen aging test.

As is clear from the above explanation, the present invention can improve hydrogen resistance not in the middle of the manufacture intermediate process of the optical fiber but after final process in a state of the optical fiber strand which can already be actually used. Therefore, it is possible to manufacture an optical fiber with an increase in transmission loss at the wavelength of 1383 nm suppressed to 0.04 dB/km or below, having excellent hydrogen resistance and transmission loss which is stable for a long period of time by low cost.

Then, this optical fiber is designed in such a way that the MFD at a wavelength of 1310 nm is 8.0 to 11.0 μm , average transmission loss at a wavelength of 1383 nm is less than average transmission loss at a wavelength of 1310 nm and dispersion at a wavelength of 1383 nm becomes +2 to +8 ps/nm/km, and therefore ~~consistency~~ the optical fiber is compatible with existing standard single mode optical fibers, ~~is also~~ guaranteed and is useful for construction of an optical network. There is an expectation for its utility as the ~~light-ray~~ optical path used in a C band WDM transmission system.

Another problem is that there are some structural defects in an optical fiber after drawing. When this optical fiber is actually used, H_2 generated from the coating of the optical fiber ~~may be~~ and the like spread within into the optical fiber, cross-react with the structural defects and generate OH groups.

Therefore, even if no OH group existed when the fiber was manufactured, new OH groups may be generated ~~when the fiber~~

~~is actually used~~ in the field, causing absorption loss in the optical fiber.

Such a problem with absorption loss by the OH groups and H₂ causes an increase in transmission loss when a long
5 transmission path is constructed using optical fibers, and ~~this is the problem that~~ must be solved without fail.

Furthermore, Japanese Examined Patent Publication No. HEI 4-4988 proposes an optical fiber which has moved the
[[light]] optical absorption wavelength toward the longer
10 wavelength side than the wavelength band of 1550 nm by substituting residual OH groups in glass by OD groups (D: deuterium). However, the actual problem is that this method causes the residual OH groups to be substituted by the OD groups, which requires processing for a long time at a high temperature,
15 which is not economical and lacks in practicality.

Furthermore, Japanese Published Patent Application ~~Laid-Open~~ No. 2000-187733 discloses the following method. This is the method that exposes the optical fiber after drawing to a deuterium ~~[[D₂]]~~ (D₂) atmosphere prior to its actual
20 use ~~and generates~~ to generate OD groups in the structural defects ~~after drawing in a stage~~ and prior to generating OH groups with H₂ in the operating environment. This prevents cross-reaction between the structural defects of the optical fiber and H₂ in the operating environment and prevents new
25 OH groups from being generated.

The development of this prior art allows optical absorption based on H₂ molecules at a wavelength of 1240 nm and optical absorption based on OH groups at a wavelength of

1400 nm to be ~~controlled~~ suppressed. However Meanwhile, when the optical fiber after drawing is exposed to a deuterium $[[D_2]]$ D_2 atmosphere, $[[D_2]]$ D_2 molecules are spread into glass. Then, absorption loss by the OD groups generated in
5 the cross-reaction with the structural defects in glass occurs on the longer wavelength side than the wavelength band of 1550 nm. At the same time, absorption loss by free $[[D_2]]$ D_2 molecules themselves occurs in the vicinity of wavelength of 1420 nm. Then, though absorption loss by these $[[D_2]]$ D_2
10 molecules is small, it will increase apparent transmission loss of the optical fiber.

This will cause the following problems. First, as described above, absorption of the OH groups occurs in at a wavelength band of 1400 nm. Therefore, ~~the absorption of~~
15 although the problem of absorption due to the OH groups in the wavelength band of 1400 nm should have already been solved through by deuterium processing (hereinafter referred to as "[[D₂]] D₂ processing"), but an increase in the above described transmission loss is observed in the optical fiber after D₂
20 processing, which may cause the observer to judge that OH groups exist in this optical fiber the observer may judge that OH groups exist in the optical fiber because of an increase in the transmission loss observed even after D₂ exposing.

As a result, further $[[D_2]]$ D_2 processing may be continued
25 using extremely expensive $[[D_2]]$ D_2 . This means that although OD groups are actually generated in all structural defects due to $[[D_2]]$ D_2 processing, ~~that is,~~ the above described phenomenon of an increase in transmission loss based on the

absorption loss of $[[D_2]]$ D_2 molecules is misidentified as being based on OH group absorption due to the presence of the OH groups. This is because no standard for defining the appropriate time point at which $[[D_2]]$ D_2 processing ends has
5 been established yet.

Therefore, a method of manufacturing an optical fiber should be provided which will solve the above described problem and define an appropriate time point at which $[[D_2]]$ D_2 processing ends based on new knowledge about the behavior of
10 $[[light]]$ absorption due to $[[D_2]]$ D_2 molecules after $[[D_2]]$ D_2 processing.

The present invention provides a method of manufacturing an optical fiber including a step of carrying out deuterium processing on an optical fiber after drawing, characterized
15 by having a time point at which the difference between 1) the difference between the average transmission loss at the wavelength of 1383 nm and the average transmission loss at the wavelength of 1420 nm of the optical fiber before deuterium processing, and 2) the difference between the average
20 transmission loss at the wavelength of 1383 nm and the average transmission loss at the wavelength of 1420 nm of the optical fiber after deuterium processing is 0.01 dB/km or more.

More specifically, the present invention provides a method of manufacturing an optical fiber which provides a time
25 interval of 48 hours or more from the time point at which the deuterium processing ~~is started~~ starts to the time point at which the measurement of average transmission loss ~~is measured~~ for the optical fiber is taken, at 25°C.

In the following explanations, the "wavelength band of 1400 nm" means ~~an arbitrary point at the wavelength~~ a wavelength within a wavelength range of 1335 to 1435 nm and the "wavelength band of 1550 nm" means ~~an arbitrary point at the wavelength~~ a wavelength within a wavelength range of 1500 to 1600 nm.
Furthermore, ~~[[D2]] D₂ processing refers to exposure of exposing of the optical fiber to a [[D2]] D₂ atmosphere which has a higher concentration than that in the ordinary atmosphere.~~

One example of an optical fiber transmission loss spectral diagram obtained by ~~applying~~ drawing ~~[[to]]~~ the optical fiber ~~base material~~ preform manufactured using a ~~normal~~ usual method is shown in FIG. 7.

In this spectral diagram, the peak appearing in the vicinity of a wavelength of 1383 nm is transmission loss caused by OH groups and this optical fiber is ready for optical transmission in both the wavelength band of 1400 nm and wavelength band of 1550 nm.

Then, the above described optical fiber is subjected to ~~[[D2]] D₂ processing~~ for 72 hours after the commencement of D₂ and a transmission loss spectral diagram of the ~~processed exposed~~ optical fiber ~~72 hours after the D₂ processing is started~~ is shown in FIG. 8.

The ~~[[D2]] D₂ processing~~ is carried out in such a way that the optical fiber to be processed is housed in a sealed container ~~[[,]] of N₂, [[etc.]]~~ for example, containing ~~[[D2]] D₂ of a predetermined concentration is sealed in the container and left as is~~ for a desired time.

As is apparent from FIG. 8, new transmission loss (A) appears in the vicinity of wavelength of 1420 nm and ~~[[other]]~~ another new transmission loss (B) also appears in the vicinity of wavelength of 1500 nm. The latter is ~~based on~~ due to the generation of absorption loss by OD groups made up of deuterium atoms D coupled with structural defects in the optical fiber before the ~~[[D2]]~~ D₂ processing.

~~[[Then]]~~ Meanwhile, the former is due to an increase of loss caused by ~~[[light]]~~ optical absorption ~~[[of]]~~ by the ~~[[D2]]~~ D₂ molecules themselves ~~spread in~~ spreading to the optical fiber.

Thus, the present ~~inventor et al.~~ inventors measured transmission loss (A) over time at a wavelength of 1420 nm after the commencement of ~~[[D2]]~~ D₂ processing ~~started~~, subtracted transmission loss before the ~~[[D2]]~~ D₂ processing from the measured values at various time points and examined the relationship between the amount of variation of transmission loss and ~~[[D2]]~~ D₂ processing time. The result is shown in FIG. 9.

As is apparent from FIG. 9, the moment the ~~[[D2]]~~ D₂ processing is started, transmission loss increases drastically compared to the value before the ~~[[D2]]~~ D₂ processing and reaches a maximum when a processing time of 72 hours has elapsed. From then on the transmission loss (A) decreases gradually.

From this new knowledge, the following points can be considered:

(1) The moment the $[[D_2]]$ D_2 processing is started, $[[D_2]]$ D_2 molecules start to spread $[[in]]$ into the optical fiber until they are saturated. For that reason, the absorption loss by $[[D_2]]$ D_2 molecules increases compared to the state before the $[[D_2]]$ D_2 processing and the transmission loss of the optical fiber increases drastically.

(2) Then, from the saturation state on, some portions of $[[D_2]]$ D_2 cross-react with structural defects and are $[[fixed]]$ coupled as OD groups sequentially, and therefore the amount of $[[D_2]]$ D_2 molecules in the optical fiber decreases sequentially and the absorption loss also decreases accordingly. On the contrary, the transmission loss increases with the absorption loss of OD groups.

(3) Then, after all structural defects have become OD groups, the residual $[[D_2]]$ D_2 molecules have no counterparts of reaction and therefore they escape out of the optical fiber. This escaping behavior is considered to have a balancing relationship with the spreading behavior from outside to inside of the optical fiber.

(4) Therefore, when a certain time elapses from the $[[D_2]]$ D_2 processing, at a certain time point at which the transmission loss of the $[[D_2]]$ D_2 -processed optical fiber turns to a decrease, the structural defects have already completed the coupling with the OD groups, and therefore that time point can be regarded as the time point at which the $[[D_2]]$ D_2 processing has ended.

An improved method of manufacturing an optical fiber has been developed based on the above described new knowledge and considerations.

More specifically, from before to after the $[[D_2]]$ D_2 processing, the average transmission loss "a" (~~suppose a unit:~~ dB/km) at a wavelength of 1383 nm is measured and at the same time the average transmission loss "b" (~~suppose b unit:~~ dB/km) at a wavelength of 1420 nm is measured and the time point at which the difference of "a-b" from before to after the $[[D_2]]$ D_2 processing ~~of a-b~~ falls below 0.004 dB/km is regarded as the time point at which the $[[D_2]]$ D_2 processing ends.

Here, the wavelength of 1383 nm is selected because this wavelength is the wavelength indicating an absorption peak ~~specific~~ due to OH groups and the loss is hardly changed due to influences of the $[[D_2]]$ D_2 processing. The wavelength of 1420 nm is selected because it is possible to check from ~~this variation in wavelength loss~~ the loss change whether $[[D_2]]$ D_2 molecules have reached the core or not. Furthermore, the $[[a-b]]$ "a-b" value is set to 0.01 dB/km or below because it is necessary to confirm that $[[D_2]]$ D_2 have securely entered the core.

More specifically, by leaving the fiber at temperature 25°C for 48 hours or more after the $[[D_2]]$ D_2 processing is started, the above $[[a-b]]$ "a-b" value can be set to 0.01 dB/km or more.

The optical fiber satisfying the above described condition, when the fiber length is 10 km or more, is an optical

fiber whose cable cutoff wavelength at a length of 22 m is 1300 nm or below.

When the average transmission loss of the optical fiber after the $[[D2]]$ D_2 processing is measured, it is preferable
5 to leave the optical fiber in an atmosphere whose concentration is lower than the maximum concentration of $[[D2]]$ D_2 during the $[[D2]]$ D_2 processing for 300 hours or more. This is because the balancing relationship between the escaping and spreading of the aforementioned $[[D2]]$ D_2 molecules is collapsed toward
10 the escape side and $[[D2]]$ D_2 molecules escape to the outside, and the absorption loss caused by free $[[D2]]$ D_2 molecules in the optical fiber practically disappears.

As is apparent from the above described explanation, the present invention allows the time point at which the $[[D2]]$
15 D_2 processing completes to be appropriately determined. Then, OH group absorption is also suppressed in a wide wavelength range of 1400 to 1550 nm and it is possible to manufacture an optical fiber usable for CWDM transmission.

Furthermore, when the average transmission loss of the
20 optical fiber after the $[[D2]]$ D_2 processing is measured, it is also possible to discern whether the average transmission loss increase is ~~based on~~ caused due to the absorption loss of $[[D2]]$ D_2 molecules or other factors such as bending loss, etc.

25 Another problem is that even when an optical fiber is manufactured using high purity silica, only OH groups of on the order of 0.1 ppm normally exist in the optical fiber but there is a variation over time in the generation of OH groups.

That is, after drawing, even if the optical fiber with fewer OH groups is laid and actually used[[, it is]] at a temperature of ordinary environment, the optical fiber exposed to surrounding a hydrogen outside at an ambient temperature, the hydrogen spreads into the optical fiber and forms OH groups and transmission loss at wavelength in the wavelength range of 1300 nm to 1600 nm, and wavelength particularly 1380 nm to 1600 nm, in particular is known to increase over time. The variation over time of transmission loss caused by the presence of this hydrogen is normally called "hydrogen ~~secular variation~~ aging loss."

Influences of such hydrogen ~~spread is~~ spreading are even observed through the cladding when optical fibers are ~~bundled as a communication accommodated into a telecommunication cable~~. This hydrogen spreading is also ~~already~~ observed even when the fiber is exposed to an atmosphere ~~of trace~~ containing a very small quantity of hydrogen on the order of 0.01% at a ~~normal~~ an ordinary temperature and the loss of, for example, 0.02 dB/km to 0.12 dB/km is observed at a wavelength of 1383 nm.

~~On the other hand~~ Meanwhile, hydrogen is believed to be generated based on by a corrosion phenomenon due to heterogeneous metal which exists in the optical cable ~~and ambient humidity or is believed to be generated under an ordinary humidity or~~ by heated silicon resin which makes up the coating. In the case of the optical fiber laid in the seawater or in the atmosphere, there is a problem that it has particularly large "hydrogen ~~secular variation~~ aging loss".

With respect to these problems, ~~prior to the actual use of an optical fiber~~ in the Japanese Published Patent Application No. 2002-148450, there is a proposal of $[[D2]]$ D_2 processing whereby prior to its actual use, the optical
5 fiber is exposed to a deuterium $[[D2]]$ (D_2) atmosphere and then left standing in the atmosphere (e.g., see Japanese Published Patent Application Laid-Open No. 2002-148450).

This method is intended to eliminate causes for generation of OH groups in actual use by letting $[[D2]]$ D_2 react with
10 structural defects and OH groups which exist in the optical fiber after drawing and then leaving them standing for a predetermined time and thereby prevent transmission loss based on increase due to the generation of OH groups ~~from increasing~~.

However, in the case of the $[[D2]]$ D_2 processing described
15 in the above described patent document $[[1]]$, the problem is that the $[[D2]]$ D_2 processing time is very long and the time during which $[[D2]]$ D_2 molecules which have been spread into the optical fiber through $[[D2]]$ D_2 processing and remain without reacting with OH groups are left standing so as to
20 escape out of the optical fiber is also very long. Thus, the above described prior art results in low production efficiency in actual industrial production and cannot be necessarily considered as a satisfactory method in practicality.

For this reason, ~~there is a demand for provision of it~~
25 is required to provide a method of manufacturing an optical fiber which solves the above described problems in the conventional $[[D2]]$ D_2 processing, carries out $[[D2]]$ D_2 processing quickly and efficiently and secures long-term

~~stability~~ reliability of the transmission characteristic characteristics.

In order to attain the above described object, the present invention provides a method of manufacturing an optical fiber characterized in that an optical fiber ~~immediately~~ after being drawn and wound around a bobbin is immediately exposed to a gas atmosphere containing a deuterium gas and then rewound around another bobbin while applying tensile tension thereto before the deuterium gas in the optical fiber is fully drained
10 degassed.

In that case, the tensile tension ~~[[is]]~~ preferably ~~equivalent~~ corresponds to 0.5 to 2% in terms of an elongation value of the optical fiber and when the optical fiber is rewound, the optical fiber is preferably cut and ~~split to a desired~~
15 length divided into lengths in the longitudinal direction.

In an example of implementation of the method of the present invention, an optical fiber ~~base material~~ preform is drawn using a normal method and coated, the ~~coated~~ optical fiber is wound around a bobbin and immediately subjected to
20 ~~[[D2]]~~ D₂ processing. More specifically, this example is implemented in such a way that the bobbin immediately after winding the optical fiber ~~is wound~~ is housed in a sealed container, a gas containing ~~[[D2]]~~ D₂ is sealed into the container and left as is for a predetermined time.

25 As the ambient gas, for example, a mixed gas of air or inert gas (He, Ar, N₂, etc.) ~~and D₂~~ with D₂ is used and in that case, it is preferably a gas containing 0.01 to 100% ~~[[D2]]~~ D₂. The mixed gas containing almost 100% ~~[[D2]]~~ D₂ can suppress

an increase in transmission loss even through short-time processing and is preferable in terms of processing high production efficiency.

5 The processing time less than 1 hour cannot allow the effect of the $[[D_2]]$ D_2 processing to be demonstrated fully and the effect reaches saturation even after 10 hours and reduces the production efficiency needlessly, and therefore the processing time is preferably 1 to 10 hours. It is more preferably around 2 hours.

10 When the temperature during the $[[D_2]]$ D_2 processing is too low, the reaction of $[[D_2]]$ D_2 processing becomes slower, whereas when the temperature is too high, the processing time may be shortened but ~~there is a danger that~~ the coating may be deteriorated, and therefore the temperature during the
15 processing is preferably controlled to within the range of $25 \pm 3^\circ\text{C}$.

After the $[[D_2]]$ D_2 processing, the processed optical fiber is rewound around another bobbin immediately. At this time, tensile tension should be applied to the optical fiber.

20 That is, a great feature of the present invention is that it is possible to omit the step of leaving the fiber as it is for a long time after $[[D_2]]$ D_2 processing for ~~draining~~ degassing the ~~gas of free- D_2~~ D_2 molecules as in the case of the conventional art.

25 This rewinding can be executed not only in an air-conditioned atmosphere but also in a nitrogen containing atmosphere.

Then, when tensile tension is applied to the optical fiber, [[a load]] the tension is also applied to the coating and the temperature of the optical fiber ~~core (glass)~~ may increase increase a little by flexion and friction energy of the coating.

5 Furthermore, ~~tensile~~ the tension is also applied to the core of the optical fiber ~~core (glass)~~. [[and]] Therefore since the [[D2]] D₂ concentration on the surface of the core of the optical fiber ~~core is~~ becomes zero or very close to zero, the residual [[D2]] D₂ molecules inside the core is likely to escape
10 to the outside, which shortens the time required for ~~gas-~~
draining degassing.

The tensile tension applied at this time is set to a level such that an elongation of the optical fiber is 0.5 to 2.5%. This is because in the case of the application of tension
15 corresponding to an elongation less than 0.5%, the above described effect cannot be obtained, while in the case of the application of tension corresponding to an elongation greater than 2.5%, ~~there is a danger that~~ the coating may be damaged. Furthermore, during this rewinding, cutting and dividing the
20 optical fiber into a ~~desired~~ predetermined length eliminates the need for providing an additional cutting/~~splitting~~ dividing step [[and]] , which is therefore efficient.

An optical fiber ~~base material~~ preform was drawn and an optical fiber was manufactured using a conventional method
25 and ~~this was~~ wound around a bobbin. One example of a transmission loss spectral diagram of this optical fiber is shown in FIG. 10. In FIG. 10, a peak A0 appearing in the vicinity

of wavelength of 1380 nm is a transmission loss caused by OH groups.

Then, the bobbin was placed in a sealed container and a gas of $[[D_2]]$ D_2 100% and $[[N_2]]$ N_2 0% was sealed therein
5 and left standing at a temperature of 25°C for two hours and $[[D_2]]$ D_2 processing was performed. After the $[[D_2]]$ D_2 processing under the above described condition, the optical fiber was left standing for 72 hours and its transmission loss was measured. The result is shown in FIG. 11. As is apparent
10 from the transmission loss spectral diagram in FIG. 11, a new peak A1 appears in the vicinity of wavelength of 1420 nm and a new broad peak A2 also appears in the vicinity of wavelength of 1500 nm. The former A1 is an increase of loss caused by absorption by $[[D_2]]$ D_2 molecules themselves spread in the
15 optical fiber and the latter A2 is ~~based on the~~ due to absorption loss due to OD groups formed by coupling structural defects $[[and]]$ with deuterium atoms D before $[[D_2]]$ D_2 processing.

Then, the optical fiber around the bobbin was rewound around another bobbin in the atmosphere. At this time, tensile
20 tension was applied to the optical fiber so that its elongation reached 1.1% and cut and separated every 25.26 km. Then, transmission loss at the wavelength of 1420 nm after $[[D_2]]$ D_2 processing ~~was started~~ was measured over time, the transmission loss before the $[[D_2]]$ D_2 processing (value at
25 1420 nm in FIG. 10) was subtracted from the measured value at that time point, a relationship between the amount of variation and elapsed time after the $[[D_2]]$ D_2 processing was examined and expressed with -●-.

Furthermore, for comparison, the optical fiber after the
[[D2]] D_2 processing was left as it is in the atmosphere without
being rewound around another bobbin and the relationship
between the amount of variation of transmission loss and
5 elapsed time after the [[D2]] D_2 processing was examined in
that case, too. The result was expressed with -x-.

As is apparent from FIG. 12, it is appreciated that with
the optical fiber manufactured according to the method in the
example, free [[D2]] D_2 molecules showing absorption loss in
10 the vicinity of wavelength of 1420 nm escaped in a shorter
time than the optical fiber manufactured according to the
method in the comparative example.

As is apparent from the above described explanation, when
an attempt is made to manufacture an optical fiber whose
15 "hydrogen secular-variation aging loss" is reduced due to
[[D2]] D_2 processing, this object can be achieved without
leaving the fiber as it is for a long time after the [[D2]]
 D_2 processing as in the case of the conventional art. This
is the effect brought about by the present invention by cutting,
20 ~~splitting~~ dividing and rewinding the fiber while applying
tensile tension immediately after the [[D2]] D_2 processing.

Therefore, according to the method of the present
invention, it is possible to produce an optical fiber which
does not increase transmission loss in a short time and
25 eliminate the need for a step of leaving the fiber as it is
for a long time, and thereby eliminate the need for retaining
many bobbins for rewinding the ~~cut-split~~ cut/divided optical

fibers for a long time, which will greatly contribute to practical use of $[[D_2]]$ \underline{D}_2 processing.

What is claimed is:

1. (Currently amended) An optical fiber having a length of
[[1 km]] one kilometer (1 km) or more and an average transmission
5 loss [[in]] at a wavelength [[band]] of 1383 [[nm]] nanometer
(nm) less than average transmission loss [[in]] at a wavelength
[[band]] of 1310 nm,

wherein the maximum value of transmission loss at the
10 wavelength of 1383 nm in any 1 km section taken along the optical
fiber less in the 1383 nm does not exceed [[the]] an average
transmission loss at the wavelength of 1383 nm over the entire
length of the optical fiber by 0.03 dB/km or more.

- 15 2. (Currently amended) The optical fiber according to claim
1, wherein the maximum value of transmission loss at the
wavelength of 1383 nm in any 1 km section ~~less in the wavelength~~
~~band of 1383 nm~~ does not exceed the average transmission loss
at the wavelength of 1383 nm by 0.01 dB/km or more.

20

3. (Currently amended) The optical fiber according to claim
1, wherein a cable cutoff wavelength at a length of 22 [[m]]
meter (m) is less than 1380 nm.

- 25 4. (Currently amended) The optical fiber according to claim
1, wherein the average transmission loss at the wavelength
of 1383 nm is less than the transmission loss [[of]] at the
wavelength of 1310 nm after hydrogen ageing aging.

5. (Currently amended) An optical fiber having an MFD of
8 $[\mu\text{m}]$ micrometer (μm) or more at 1310 nm, $[\text{no}]$ zero
dispersion wavelength $[\text{in}]$ out of a wavelength range of 1280
5 to 1324 nm, a dispersion ~~absolute value~~ in said wavelength
range of 0.1 to 8.0 ~~ps/nm/km~~ picosecond/nanometer/kilometer
(ps/nm/km) in absolute value, a dispersion slope of 0.1
~~ps/nm²/km~~ picosecond/nanometer²/kilometer (ps/nm²/km) or less,
a cutoff wavelength ~~of 1270 nm or less~~ determined according
10 to a 22 m method not more than 1270 nm and an average transmission
loss at the wavelength of 1310 nm of 0.4 dB/km or less.

6. (Currently amended) The optical fiber according to claim
5, wherein $[\text{the}]$ said optical fiber has MFD at 1310 nm $[\text{is}]$
15 of 9.5 μm or less.

7. (Currently amended) The optical fiber according to claim
5, wherein a zero dispersion wavelength $[\text{is}]$ exist within
a wavelength range of 1325nm to 1350 nm.

20

8. (Currently amended) The optical fiber according to claim
5, wherein $[\text{when}]$ an MFD at 1310 nm is A (μm) and a cutoff
wavelength determined according to a $[\text{2}]$ 22 m method is B
(nm), with satisfying $A \times B \leq 11 \times 1000$.

25

9. (Original) The optical fiber according to claim 5, wherein
an average transmission loss at the wavelength of 1383 nm is

less than an average transmission loss at the wavelength of 1310 nm.

10. (Currently amended) The optical fiber according to claim 5 9, wherein an increase in transmission loss at wavelength of 1383 nm ~~from before to after~~ after ~~[[a]] hydrogen ageing test~~ aging is 0.04 dB/km or less.

11. (Currently amended) A manufacturing method of an optical 10 fiber having a mode field diameter of 8.0 to 11.0 μm at a wavelength of 1310 nm, an average transmission loss at a wavelength of 1383 nm less than an average transmission loss at a wavelength of 1310nm, and a dispersion of +2 to +8 ps/nm/km at the wavelength of 1383 nm, comprising ~~the steps of:~~

15 drawing the optical fiber from an optical fiber perform~~[[,]]~~;
applying coating resins on said optical fiber~~[[,]]~~; and
exposing said optical fiber to a deuterium containing
20 atmosphere.

12. (Original) The manufacturing method of an optical fiber according to claim 11, wherein the optical fiber has a dispersion of +4 to +7 ps/nm/km at a wavelength of 1383 nm.

25 13. (Currently amended) The manufacturing method of an optical fiber according to claim 11, wherein said ~~[[steps]]~~ step of exposing is performed by exposing the optical fiber

to the deuterium containing atmosphere under an ordinary pressure at an ordinary temperature and under an ordinary pressure.

5 14. (Currently amended) The manufacturing method of an optical fiber according to claim 13, wherein the ~~processing~~ exposing time in said ~~[[steps]]~~ step of exposing is 24 hours at longest.

10 15. (Currently amended) The manufacturing method of an optical fiber according to claim 11, wherein ~~said optical fiber has an amount of increase in transmission loss of 0.04 dB/km or less at the wavelength of 1383 nm when a hydrogen ageing test is conducted on said optical fiber~~ an increase in
15 transmission loss at the wavelength of 1383 nm after hydrogen aging is 0.04 dB/km or less.

16. (Currently amended) The manufacturing method of an optical fiber according to claim 11, wherein ~~when a hydrogen ageing test is conducted on said optical fiber, said optical fiber has an amount of increase in average transmission loss of 0.01 dB/km or less at the wavelength of 1383 nm~~ an increase in transmission loss at the wavelength of 1383 nm after hydrogen
20 aging is 0.01 dB/km or less.

25

17. (Currently amended) A manufacturing method of an optical fiber, including ~~a deuterium processing on the optical fiber after drawing, characterized by a time point at which a~~

~~difference between an exposing step of exposing the optical fiber after drawing to a deuterium containing atmosphere, wherein a difference [[of]] between average transmission losses respectively at the wavelengths of 1385 nm and 1420nm before deuterium processing and said exposing step becomes different from a difference [[of]] between average transmission losses respectively at the wavelengths of 1385 nm and 1420nm after deuterium processing is said exposing step, by 0.01dB/km or more at least one time.~~

10

18. (Currently amended) The manufacturing method of an optical fiber according to claim 17, wherein a time interval ~~of 48 hours or more is provided for said optical fiber at 25°C from the time point at which said deuterium processing is~~ started to the time point at which said transmission loss is measured is 48 hours or more at 25°C.

15

19. (Currently amended) The manufacturing method of an optical fiber according to claim 17, wherein the ~~inspection~~ length of the optical fiber is 10 km or more and a cable cutoff wavelength at a length of 22 m of 1300 nm or less.

20

20. (Currently amended) A manufacturing method of an optical fiber, comprising ~~the steps of:~~

25

drawing the optical fiber from an optical fiber perform[[,]];
winding said optical fiber around a bobbin[[,]]; and [[then]]

immediately exposing said optical fiber to a deuterium containing atmosphere, wherein

said optical fiber is rewound around another bobbin while
5 applying tensile tension, before said deuterium is completely degassed from said optical fiber.

21. (Original) The manufacturing method of an optical fiber according to claim 20, wherein said tensile tension corresponds
10 to 0.5% to 2% in tensile strain of the optical fiber.

22. (Original) The manufacturing method of an optical fiber according to claim 20, wherein said optical fiber is cut and divided into predetermined lengths in the longitudinal
15 direction when said optical fiber is rewound.

ABSTRACT OF THE DISCLOSURE

An optical fiber having a length of ~~[[1 km]]~~ one kilometer or more with average transmission loss ~~[[in]]~~ at a wavelength ~~[[band]]~~ of 1383 nm being less than average transmission loss ~~[[in]]~~ at a wavelength ~~[[band]]~~ of 1310 nm,

wherein a maximum value of a transmission loss at the wavelength of 1383 nm of any ~~[[1 km]]~~ one kilometer section ~~loss in the wavelength band of 1383 nm~~ along the entire length of the optical fiber does not exceed the average transmission loss at the wavelength of 1383 nm along the entire length of the optical fiber by 0.03 dB/km or more.
